## Functional Description

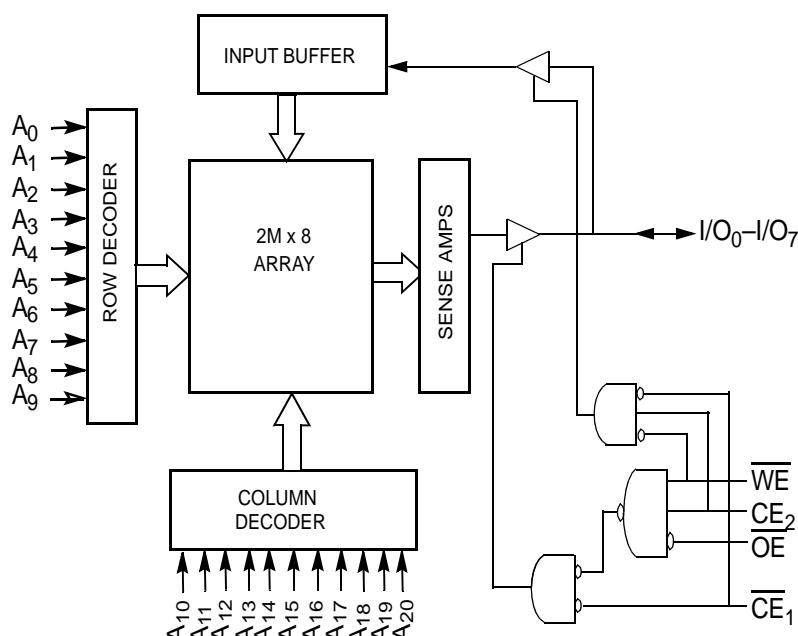

The CY7C1069DV33 is a high-performance CMOS Static RAM organized as 2,097,152 words by 8 bits. Writing to the device is accomplished by enabling the chip (by taking  $CE_1$  LOW and  $CE_2$  HIGH) and Write Enable (WE) inputs LOW.

Reading from the device is accomplished by enabling the chip ( $CE_1$  LOW and  $CE_2$  HIGH) as well as forcing the Output Enable (OE) LOW while forcing the Write Enable (WE) HIGH. See the truth table at the back of this data sheet for a complete description of Read and Write modes.

The input/output pins ( $I/O_0$  through  $I/O_7$ ) are placed in a high-impedance state when the device is deselected ( $CE_1$  HIGH or  $CE_2$  LOW), the outputs are disabled (OE HIGH), or during a Write operation ( $CE_1$  LOW,  $CE_2$  HIGH, and WE LOW).

The CY7C1069DV33 is available in a 54-pin TSOP II package with center power and ground (revolutionary) pinout, and a 48-ball very fine-pitch ball grid array (VFBGA) package.

## AC Test Loads and Waveforms<sup>[4]</sup>

### Notes:

2.  $V_{\text{IL}}$  (min.) =  $-2.0\text{V}$  and  $V_{\text{IH}}$  (max.) =  $V_{\text{CC}} + 2\text{V}$  for pulse durations of less than 20 ns.

3. Tested initially and after any design or process changes that may affect these parameters.

4. Valid SRAM operation does not occur until the power supplies have reached the minimum operating  $V_{\text{DD}}$  ( $3.0\text{V}$ ).  $100\mu\text{s}$  ( $t_{\text{power}}$ ) after reaching the minimum operating  $V_{\text{DD}}$ , normal SRAM operation can begin including reduction in  $V_{\text{DD}}$  to the data retention ( $V_{\text{CCDR}}$ ,  $2.0\text{V}$ ) voltage.

**Notes:**

5. Test conditions assume signal transition time of 3 ns or less, timing reference levels of 1.5V, input pulse levels of 0 to 3.0V. Test conditions for the Read cycle use output loading shown in part a) of the AC test loads, unless specified otherwise.
6.  $t_{\text{POWER}}$  gives the minimum amount of time that the power supply should be at typical  $V_{\text{CC}}$  values until the first memory access can be performed.
7.  $t_{\text{HZOE}}$ ,  $t_{\text{HZSCE}}$ ,  $t_{\text{HZWE}}$  and  $t_{\text{LZOE}}$ ,  $t_{\text{LZCE}}$ , and  $t_{\text{LZWE}}$  are specified with a load capacitance of 5 pF as in (b) of AC Test Loads. Transition is measured ±200 mV from steady-state voltage.
8. These parameters are guaranteed by design and are not tested.
9. The internal Write time of the memory is defined by the overlap of  $\overline{\text{CE}}_1$  LOW/ $\text{CE}_2$  HIGH, and  $\overline{\text{WE}}$  LOW.  $\overline{\text{CE}}_1$  and  $\overline{\text{WE}}$  must be LOW along with  $\text{CE}_2$  HIGH to initiate a Write, and the transition of any of these signals can terminate the Write. The input data set-up and hold timing should be referenced to the leading edge of the signal that terminates the Write.
10. The minimum Write cycle time for Write Cycle No. 3 ( $\overline{\text{WE}}$  controlled,  $\overline{\text{OE}}$  LOW) is the sum of  $t_{\text{HZWE}}$  and  $t_{\text{SD}}$ .

12. Device is continuously selected.  $\overline{CE}_1 = V_{IL}$ ,  $CE_2 = V_{IH}$ .

**Notes:**

 15. Data I/O is high-impedance if  $\overline{OE} = V_{IH}$ .

 16. If  $\overline{CE}_1$  goes HIGH/ $\overline{CE}_2$  LOW simultaneously with  $\overline{WE}$  going HIGH, the output remains in a high-impedance state.

 17. CE above is defined as a combination of  $\overline{CE}_1$  and  $\overline{CE}_2$ . It is active low.
